(57) Abstract:

PROBLEM TO BE SOLVED: To prevent access from an equipment, except to a specified image center equipment from being accepted by demanding a password to the access from the image center equipment through an image transmitter and accepting a request from an image center, only when a previously registered password is returned.

SOLUTION: Image center equipment 10 requests a line connection, and a modem 3 of an image transmitter 1 performs negotiation with a center side modem 11 and performs mutual recognition. The image center equipment 10 transmits data, showing an image transmission request and corresponding to the request of password from a controller 2 where these data are received, and a previously set password is returned. When the received password matches the password registered in a password register 4, the picked picked-up image of an instructed monitor camera is transmitted by the controller 2. However, when these passwords do not match, the line is disconnected. Thus, the image of monitor camera is transmitted to only specified equipment.
